## Background

EGFR; also named as ERBB1; is a cell-surface receptor for members of the epidermal growth factor family (EGF-family) of extracellular protein ligands. Binding of the protein to a ligand induces receptor dimerization and tyrosine autophosphorylation and leads to cell proliferation. The gene resides on chromosome 7p12; encoding a 170 kDa membrane-associated glycoprotein. Recent studies have shown EGFR plays a critical role in cancer development and progression; including cell proliferation; apoptosis; angiogenesis; and metastatic spread. Mutations in this gene are associated with lung cancer.
